

1. What do we do to a Python statement that is immediately after an if statement to indicate that the statement is to be executed only when the if statement is true? 1 / 1 point

Select the correct option.

- ☐ Begin the statement with a curly brace {
- ☐ Underline all of the conditional code
- ☐ Start the statement with a "#" character
- ☒ Indent the line below the if statement

Nice work

Correct! In Python, the statement following an if is indented to indicate it should be executed when the condition is true.

2. Which of these is not a comparison / logical operator? 1 / 1 point

Select the correct option.

- ☐ !=
- ☐ >=
- ☐ <=
- ☒ =
- ☐ ==

Nice work

Correct! = is an assignment operator, not a comparison or logical operator.

3. What is true about the following code segment? 1 / 1 point

```
1 if x == 5 :
2     print('Is 5')
3     print('Is still 5')
4     print('Third 5')
```

Select the correct option.

- ☒ Depending on the value of x, either all three of the print statements will execute or none of the statements will execute
- ☐ The string 'Is 5' will always print out regardless of the value for x.
- ☐ The string 'Is 5' will never print out regardless of the value for x.
- ☐ Only two of the three print statements will print out if the value of x is less than zero.

Nice work

Correct! The indent level indicates all three statements will execute if the condition x == 5 is true; otherwise, none will execute.

4. When you have multiple lines in an if block, how do you indicate the end of the if block? 1 / 1 point

Select the correct option.

- ☐ You capitalize the first letter of the line following the end of the if block
- ☐ You omit the semicolon ; on the last line of the if block
- ☒ You de-indent the next line past the if block to the same level of indent as the original if statement
- ☐ You use a curly brace { after the last line of the if block

Nice work

Correct! Python uses indentation to define blocks of code, and de-indentation signifies the end of the block.

5. You look at the following text: 1 / 1 point

```
1 if x == 6 :
2     print('Is 6')
3     print('Is Still 6')
4     print('Third 6')
```

It looks perfect but Python is giving you an 'Indentation Error' on the second print statement. What is the most likely reason?

Select the correct option.

- ☐ In order to make humans feel inadequate, Python randomly emits 'Indentation Errors' on perfectly good code. After about an hour the error will just go away without any changes to your program.
- ☐ Python has reached its limit on the largest Python program that can be run.
- ☒ You have mixed tabs and spaces in the file
- ☐ Python thinks 'Still' is a mis-spelled word in the string.

Nice work

Correct! Mixing tabs and spaces can cause indentation errors even if the code looks correct.

6. What is the Python reserved word that we use in two-way if tests to indicate the block of code that is to be executed if the logical test is false? 1 / 1 point

- ☐ except
- ☒ else
- ☐ iterate
- ☐ break

Nice work

Correct! The **else** keyword defines a block of code to be executed when the if condition is false.

7. What will the following code print out? 1 / 1 point

```
1 x = 0
2 if x < 2 :
3     print('Small')
4 elif x < 10 :
5     print('Medium')
6 else :
7     print('LARGE')
8 print('All done')
```

Select the correct option.

- ☒ Small
- ☐ All done
- ☐ Small
- ☐ LARGE
- ☐ All done
- ☐ Small
- ☐ Medium
- ☐ LARGE
- ☐ All done

Nice work

Correct! The condition x < 2 is true, so it prints "Small". The next statement outside the conditional structure prints "All done".

8. For the following code, 1 / 1 point

```
1 if x < 2 :
2     print('Below 2')
3 elif x >= 2 :
4     print('Two or more')
5 else :
6     print('Something else')
```

What value of 'x' will cause 'Something else' to print out?

Select the correct option.

- ☐ x = 2.0
- ☒ This code will never print 'Something else' regardless of the value for 'x'
- ☐ x = 22
- ☐ x = -2.0

Nice work

Correct! The logic covers all possible values of x. The else block will never be executed.

9. In the following code (numbers added), what will be the last line to execute successfully? 1 / 1 point

```
1 (1)  astr = 'Hello Bob'
2 (2)  istr = int(astr)
3 (3)  print('First', istr)
4 (4)  astr = '123'
5 (5)  istr = int(astr)
6 (6)  print('Second', istr)
```

Select the correct option.

- ☒ 1
- ☐ 6
- ☐ 5
- ☐ 2

Nice work

Correct! The first line assigns a string to **astr** successfully.

10. For the following code: 1 / 1 point

```
1 astr = 'Hello Bob'
2 istr = 0
3 try:
4     istr = int(astr)
5 except:
6     istr = -1
```

What will the value be for istr after this code executes?

Select the correct option.

- ☐ false
- ☐ It will be a random number depending on the operating system the program runs on
- ☐ It will be the 'Not a number' value (i.e. NaN)
- ☒ -1

Nice work

Correct! The **except** block assigns -1 to istr because converting 'Hello Bob' to an integer fails.
